

Enterprise RAG System - Version 3

Topic: Keyword Search

Version 3 introduces keyword-based retrieval. Keyword search scans every text chunk and returns the chunks that contain the user's query. Example keywords: Python Artificial Intelligence Automation Data Science Machine Learning Python is a popular programming language used for web development, automation, artificial intelligence, data science, scripting, and backend development. A Retrieval-Augmented Generation (RAG) system first reads documents, splits them into chunks, performs keyword or semantic search, retrieves the most relevant chunks, and then sends those chunks to a Large Language Model to generate an answer. Keyword search is simple, fast, and easy to understand, but it cannot understand meaning or context. Later versions of this project will replace keyword search with embeddings and semantic search.
